Explanation of Symbols used in this Document

To enable optimal usage of this manual and safe operation of the device during installation, operation and maintenance routines, please note the following description of symbols:

This indicates a feature that is important either for optimal and comfortable usage or optimal operation of the system.

Example: „Useful C routines for this purpose are on the support disk.“

This indicates a fact or feature very important for the safety of the user and/or can cause a serious hardware defect if not appropriately applied.

Example: „Disconnect the mains plug before opening the case!“

This indicates an example.

1 Introduction

You have decided to use one of the most sophisticated devices and for the most advanced modular PV system technology by purchasing a Sunny Boy® string inverter. SMA string technology has revolutionized parallel grid feeding. The SMA Sunny Boy String Inverters are the most successful photovoltaic String Inverters in Europe. They convince with their outstanding qualities concerning the efficiency and reliability and make the installation of a PV-system most simple and affordable. Sunny Boy string inverters are the universal equipment for all applications – small or large scale PV-systems.

The Sunny Boy has complete on board islanding protection and meets safety operating standards and code requirements world-wide. In North America, the Sunny Boy meets the requirements of UL 1741. NEC 690 building code requirements for photovoltaic systems will be met with the internal ground fault detector interrupter (GFDI).

In Australia Sunny Boys are certified according to the “Australian Guidelines” and the regulations of the IEC950. In the United Kingdom Sunny Boys passed the tests in accordance with the “engineering recommendation G77”. The Sunny Boys comply with all regulations from the VDEW (Association of German Electricity Producers) for the supplementary grid feeding to the low voltage electricity grid of the utility. This contains the regulations concerning the “Independent Disconnection Device” known as MSD (Mains monitoring device with allocated Switching Devices) and the regulations of the DIN VDE 0126. Furthermore the Sunny Boy complies with the according standards and the low voltage regulations as certified in the CE declaration (see appendix).

---

1 Sunny Boy is a registered Trademark of SMA Regelsysteme GmbH
2 System Description

The reduction of CO₂ emission and other pollution resulting from energy conversion is becoming more and more important. The direct conversion of solar radiation to electric energy (photovoltaics) will play a substantial role in this essential matter.

Supplementary grid feeding includes the conversion of the DC voltage from the PV-panel to grid compatible AC voltage with so-called "inverters" and the subsequent connection to the electricity grid in the house distribution.

Here the electricity from the PV-modules provides all consumers with electric power (household devices, lights etc.). In case that not enough energy is produced the additionally necessary energy is obtained from the grid. In case that there is a surplus of energy, this surplus is fed into the local grid and is therefore available for other consumers. This way every single kilowatt-hour is utilized and the electricity company’s power systems are relieved. In the most simple case a PV-system therefore consists of two basic components: the PV-panel and the inverter.

*Fig. 2.1: Grid tied string inverter application*
2.1 String Technology

The experience with several thousand grid-connected PV-systems in Europe with an output range from one to several hundred kilowatts has shown that the costs for grid connecting and monitoring the PV-system add up to almost 50% of the costs for the entire system. The reduction of these costs, especially the costs for the cabling on the DC side and the subsequent distribution on the AC side, was the reason for developing the String Technology from SMA. The Sunny Boy finally enabled the string technology to be the standard system design for PV-systems.

String technology means that a small number of PV-modules are connected in series to a "string", each string is then connected to a separate inverter which feeds the electricity of one string to the grid. Large PV-systems consist of a large number of single strings. The energy produced is collected directly on the AC side which results in the fact that the system design gets very simple and no extraordinary DC cabling is necessary anymore. String Technology allows MPP tracking for each small module group, thus improving system efficiency by 1 - 3%.

The most various system concepts can be realized with this strategy. A wide range of differently scaled inverters and peripheral components is available:

**Sunny Boy Inverters:**

- **Sunny Boy 700:**
  The small model for small PV-systems with simple extension possibilities and configurable input voltage range

- **Sunny Boy 850:**
  The output optimized inverter for PV-systems with 1 kWp

- **Sunny Boy 1100E:**
  For PV-systems with 1 kWp; supports a wider input voltage range
• **Sunny Boy 2000:**
  The transformerless string inverter with extended input voltage and increased efficiency, ideal for large PV-systems.

• **Sunny Boy 2500U:**
  The powerful string inverter with electric separation, ideal for large PV-systems.

**Additional Equipment for the Sunny Boy Inverters**

• **Sunny Display**
  Lid integrated LCD for all Sunny Boys, cyclic display of all relevant operating data

• **Sunny Data:**
  The PC-program for the communication with your Sunny Boy inverters

• **Sunny Boy Control:**
  The terminal for your PV-system for data acquisition and evaluation - for up to 50 Sunny Boys - communication via Powerline or RS232 / RS485

• **Sunny Boy Control LIGHT:**
  Terminal for PV systems with up to 20 Sunny Boys - communication via Powerline

• **Sunny Boy Control PLUS:**
  The terminal for your PV-system for data acquisition and evaluation - for up to 50 Sunny Boys - communication via Powerline or RS232 / RS485 - additional digital I/O channels for nearly any sensor type - continuous standalone data storage and remote access via modem etc.

• **Sunny Data Control:**
  The PC-program for visualization of the data from your Sunny Boy Control

The Sunny Boy Family is the result of a consequent development with SMA’s experience in PV conversion with over 60 MW of total nominal inverter output power in over 42,000 units with nominal powers from 700 W up to 500 kW (date: 03/01).
2.2 Diagnosis and Communication

The modular PV system technology leads to a spread out distribution of the Sunny Boy String inverters. A simple and fast function monitoring of the status and measured values for each single Sunny Boy is easy to achieve. The data is either displayed on the LCD of the Sunny Boy Control or is shown on the screen of a PC running the according SMA software. Two programs "Sunny Data“ and "Sunny Data Control“ are based on a comfortable Windows GUI and allow the user to process the data with other programs such as MS Excel®.

The data transmission is done via Powerline (see chapter 3.1). SMA supports the following monitoring strategies for Sunny Boy string inverters:

- PC with software package Sunny Data for small and medium size PV-systems - also for Sunny Boy Control and Sunny Boy Control Light
- Sunny Boy Control as standalone controller for nearly any PV-system size
- PC with software package Sunny Data Control for enhanced operation together with the Sunny Boy Control

These monitoring concepts support the following features:

- Continuous acquisition of operation data of all connected string inverters and their PV-panels
- Supervision of operating states and failure indication
- Spot value transmission from single Sunny Boys
- Identification of failures in the single strings
- Graphical representation of the data from single Sunny Boys or comparison of the data from several ones
- System management, transmission of operation parameters
2.3 Technical design of the Sunny Boy

The Sunny Boy inverter is based on a power unit that operates with a very high efficiency and optimal reliability. An IGBT H-bridge converts the voltage coming from the PV modules to a high frequency secondary circuit with 16 kHz. The voltage is then fed to the grid after being processed by a transformer.

![Block circuit diagram of the Sunny Boy 2500U](image)

**Fig. 2.2:** Block circuit diagram of the Sunny Boy 2500U

The Sunny Boy 2500U is designed for strings with 18 to 24 standard modules connected in series.

A micro controller manages the current control which results in a perfectly sinus wave AC current with very low harmonic distortion. Both operation with a fixed voltage or with MPP tracking is possible.

2.3.1 Ambient Temperature

The heat sink of the Sunny Boy is necessary in order to let thermal energy dissipate. Once the heat sink gets too hot the Sunny Boy reduces the output energy accordingly but nevertheless keeps feeding to the grid.
2.3.2 **Sequential Control System**

The sequential control system also manages the communication with the system monitoring tools Sunny Data and Sunny Data Control. The Sunny Boy therefore is not only a simple standalone device - it can be part of one big PV-system that has one central control and monitoring facility.

2.3.3 **Stainless Steel Case**

The case of the Sunny Boy is made of stainless steel which protects the inverter from dust and water up to enclosure type NEMA 4X. The Sunny Boy can therefore be mounted nearly anywhere inside or outside the house with an ambient temperature range of -13 °F … 140 °F (-25° C to +60 °C). All applicable standards and regulations for personnel safety and EMI are complied with.
2.3.4 Islanding Protection

Islanding protection is an essential safety issue in order to make sure that nobody working on the grid is harmed. It is important to detect an "islanding" where the public grid is not up and the electricity consumers and producers are accidentally equal - resulting in the fact that the electricity circuits are on "full blow" even though the fuses are down.

The method of Sunny Boy islanding detection includes the active grid impedance measurement has been extensively tested and proven to exceed the requirements of UL1741. In the event of a utility outage, these active measurement results in an over/under frequency or voltage condition. The Sunny Boy then is disconnected from the grid. Two independent one-chip computers monitor the grid. Each of these computers constantly monitors the grid quality by checking the frequency, voltage and grid impedance. The redundant circuit and an automatic self test on each system startup ensure a reliable function of the grid disconnection. The value of the grid impedance is the sum of the impedance of the public grid and the cabling impedance of the house (i.e. cable of the house distribution to the connection point of the Sunny Boy). It is therefore important to avoid an unnecessary increase of the grid impedance due to the connection cable to the Sunny Boy. Otherwise the grid voltage is increased to non-permissible values while the Sunny Boy feeds to the grid.

NOTE: We recommend that you have a look at the connection wire between the Sunny Boy to the house distribution with respect to the impedance increase.
2.3.5 Grid Monitoring

Conditions that cause the Sunny Boy to be disconnected from the grid:

- **Over / under AC-voltage**
  - The grid voltage may be within a range of the requirements of UL1741. Once the grid voltage exceeds this range the Sunny Boy is disconnected from the grid within 0.1 s.

- **Over / under grid frequency**
  - The grid frequency may be within a range of +0.5 to −0.7 Hz of the nominal grid frequency while the voltage is within a range of -30 % and +15 % of the nominal grid voltage $V_{AC}$ - once the frequency goes beyond this range the Sunny Boy is disconnected from the grid within 0.1 s.

- **Rate of change of frequency**
  - Once the frequency changes drastically while it is feeding to the grid, the Sunny Boy disconnects within 0.2 s.

- **Grid impedance measurement**
  - The Sunny Boy does not start to feed to the grid if the grid impedance $Z_{AC}$ is higher than an adjustable trip point.
  - The Sunny Boy is disconnected from the grid within 5 sec. once the grid impedance changes drastically within a short time or the impedance gets too high. All values are adjustable by an authorized installer.

This new Sunny Boy disconnection concept provides maximal safety with nevertheless minimal necessary installation.
2.3.6 Ground Fault Detector Interrupter (GFDI)

The GFDI is supposed to interrupt the connection to ground of the PV panel in case a ground leakage current of 1 A is exceeded. This ground fault current is the result of a ground fault of the PV panel. The inverter then has to indicate this condition and disconnect from the grid. The inverter has to be reset manually, it cannot restart automatically.

In grid-feeding mode the ground current is continuously monitored by two independent systems, the sequential control system and the current control system. If the maximum current intensity is exceeded the inverter switches to “permanent disable”-“Earth-currentmax”. This is indicated by the red and yellow LEDs.

In addition the voltage between the ground and PV-minus is monitored. If the voltage exceeds the maximum value defined the failure “GFDI Fuse Open” is displayed and the inverter stops feeding to the grid. This failure is indicated by the red LED. The “GFDI Fuse Open” failure persists in case the GFDI fuse is defective.
3 System Monitoring and Diagnosis

The monitoring and control of PV-systems is essential for the optimal energy yield, the safety of your PV-system and the long life of your PV-components.

The Sunny Boy family inverters have various options for PV-system control and monitoring. This chapter will try to cover all different possibilities for the data transmission, the cabling circuits and how to eliminate and suppress any transmission failures.

3.1 Data Transmission via Powerline

Signal transmission between the Sunny Boy and the Sunny Boy Control or the PC is done with the grid connection via powerline. This requires a minimum of installation (see below). The Sunny Boy must be equipped with a powerline modem for data transmission. The PC must be equipped with the socket modem (SWR-COM). This is already integrated in the Sunny Boy Control, the specific controller for PV-systems. The PC or the Sunny Boy Control can be positioned anywhere within the in-house network as they acquire data directly from the AC circuit.

For trouble-free operation the Sunny Boys and the PC socket modem or the Sunny Boy Control must be connected to the same phase of the in-house network. If the communicating partners are connected to different phases the communication must be established with a so-called phase coupling device. The phase coupling device is available from SMA and must be installed by qualified personnel. It will make communication within the entire in-house network possible.
Fig. 3.1: Example of data transmission via Powerline
3.2 Data Transmission with a Separate Data Cable

Data transmission via Powerline is a reliable and affordable solution. In electrical grids which are strongly influenced by high-frequency disturbance such as those in industrial sites data transmission via Powerline may not be possible. Communication between the Sunny Boys and the Sunny Boy Control or the PC can then be done with a separate data cable.

RS232 communication

If only one Sunny Boy has to be connected to the PC the easiest way is direct coupling via an RS232 port. A maximum of 15 m is permissible between the PC and the Sunny Boy.

![Fig. 3.2: Example for RS232 communication with a single Sunny Boy](image)

NOTE: RS232 communication is only suitable for data transmission between a PC and one single Sunny Boy.

NOTE: RS232 communication with a Sunny Boy is only a reasonable solution with direct connection to the PC. If a Sunny Boy Control is used instead of the PC an RS485 connection is necessary. See section “RS485 communication” for details.
**RS485 communication**

In grids loaded with high interference several Sunny Boys can be connected to a PC or the Sunny Boy Control via RS485 and a separate data cable. Data cables of up to 1200 m are permissible.

![Schematic layout of RS485 data transmission with several Sunny Boys](image)

**Fig. 3.3:** Schematic layout of RS485 data transmission with several Sunny Boys
3.3 PV-System Management and Diagnosis

Sunny Data

Sunny Data is used in order to establish a communication between a PC and your Sunny Boys and process and evaluate the data from these.

Selected measurement channels can be displayed online. The data can be displayed manually or automatically. The data is stored on any available mass storage medium. Special functions allow the installer to modify the operating parameters of the Sunny Boy in order to improve the system performance. Details are available in the Sunny Data manual.

![Sunny Data user interface](image)

**Fig. 3.4:** Sunny Data user interface
Sunny Data Control

Large PV-systems are supervised and monitored with a Sunny Boy Control. The Sunny Boy Control handles up to 50 Sunny Boys and assists the commissioning of the PV-system. Additional features are remote diagnosis via modem, fax messages and more.

The data can be collected by a PC connected to the Sunny Boy Control. Sunny Data Control is the software that manages the PV-system and can display the data in nearly any desired way.

For details see the Sunny Data Control manual.

Fig. 3.5: Sunny Data Control user interface
3.4 Measuring Channels and Messages

The communication supports a number of measuring channels and messages from the Sunny Boy inverters.

Table 3.1: Measurement accuracy of the Sunny Boy
4 Technical Data

Input (PV panel)

Maximum open circuit voltage of the PV panel

WARNING: It is essential to comply with the respective input voltage range which varies depending on the type and number of PV modules used.

WARNING: The maximum open circuit voltage of the PV panel may not exceed the specified maximum input voltage of the Sunny Boy.

The open circuit voltage of the PV panel depends on the temperature of its cells and on the respective solar radiation. The highest open circuit voltage of the PV panel occurs when the temperature of the cells is at its lowest point. Therefore it has to take into account the lowest possible ambient temperature of the PV panel when planning the PV-system. Based on this temperature and knowing the type of PV modules used you can then determine the maximum open circuit voltage of the PV panel. You can enter these data into our EXCEL® tool “GenAu“ and check whether the maximum admissible input voltage of the Sunny Boy is not exceeded under any possible operating conditions. You will find this tool in the Internet for download at:

http://www.SMA.de/ftp/energietechnik/sunnyboy/GenAu/GenAu.exe

WARNING: The MPP-voltage of the connected PV-modules may not get below the specified range at +160 °F (U_{MPP+160°F} > min. input voltage range).

NOTE: The Sunny Boy can tolerate a current higher than the specified current as long as the voltage is within the specified range.
Minimum MPP-voltage of the PV panel

Often a fixed lower MPP voltage limit of the inverter is not useful when the cells of the PV panel have very high temperatures. This means the MPP voltage of the PV panel decreases and the inverter cannot feed the maximum power from the PV panel to the low-voltage grid. The inverter remains at the lower limit of input voltage and cannot follow the MPP of the PV panel. Therefore the Sunny Boy has a flexible MPP voltage range.

There is a fixed ratio between the minimum MPP voltage $V_{MPPmin}$ the Sunny Boy loads onto the PV panel and the grid voltage $V_{AC}$ as shown in Fig. 4.1

Depending on the current grid voltage the minimum DC voltage is assessed and fixed. This flexible MPP voltage range lets the user make optimum use of the specific device characteristics while the energy yield is increased.

![Fig. 4.1: Minimum MPP-voltage as a function of grid voltage](image)
Input Values of the Sunny Boy (DC side)

Input voltage, MPP range (depending on $V_{AC}$): $V_{PV} \quad 234 \, V^{*} - 550 \, V \, DC$

Max. open circuit voltage (under all conditions): $V_{PVOC} \leq 600 \, V \, DC$

Max. input current: $I_{PV} \quad 13 \, A \, DC$

Max. DC power: $P_{PV} \quad 2710 \, W \, DC$

Recommended PV-generator power: up to $3000 \, W_p$

Voltage ripple: $V_{PP} < 10 \%$

All-pole disconnection on DC side: optional external DC-breaker

Pole confusion protection: short circuit diode

Ground fault protection: ground fault detection

$(I_{Diff} > 1000 \, mA)$

$^{*} @V_{AC nom}$
Output values of the Sunny Boy (utility side)

Nominal output power: \( P_{ACnom} \) 2200 W AC

Maximum output power: \( P_{ACmax} \) 2500 W AC

Operating range, utility voltage: \( V_{AC} \) 211 - 264 V AC

Operating range, utility frequency: \( f_{AC} \) 59.3 - 60.5 Hz

Total Harmonic Distortion (THD): \( THD_{iAC} \) < 4 %

\( (\text{with } K_{Vgrid} < 2 \%, P_{AC} > 0.5 P_{ACnom}) \)

Phase shift (ref. fundamental) \( \phi \) 0°

Utility monitoring:

- Islanding protection: \( V_{AC}; f_{AC} \) in accordance with UL 1741

- Ground Fault Protection: \( I_{DIF}; \) in accordance with UL1741

All pole disconnection utility: independent disconnection (MSD), redundant design (double)

Short circuit protection: current controlled

Overvoltage classification: III

Testing voltage (50 Hz): 2.88 kV (1 s)

Testing voltage for surge (1.2/50 µs): 4 kV (serial interface 6 kV)

External Interfaces

Data transmission via Powerline: optional

Data transmission via separate cable: optional; electrically separated RS232 / RS485
Power Consumption

Internal consumption during operation:  < 7 W
Internal consumption during stand-by:  < 0.25 W

Efficiency

Max. Efficiency:  \( \eta_{\text{max}} > 94 \% \)

Ambient Conditions

Tolerable ambient temperature:  -13 °F…140 °F ( -25 °C ... +60 °C)
Rel. humidity:  0 ... 100 %, class 3K6

Size & Weight

Enclosure type:  NEMA 4X
Size (w x h x d):  17.08 x 11.61 x 8.42 inch
               (434 x 295 x 214 mm)
Weight:  70 lb. (32 kg)

Certifications:

EMI:  in compliance with FCC regulations,
      DIN EN 50081, part 1
      (EN 55014, EN 60555 part 2,
       EN 55011 group 1, class B)
      DIN EN 50082, part 1
Utility interaction:  in compliance with UL1741,
                    EN 61000-3-2
Utility monitoring:  in compliance with UL1741,
                    optional: MSD (VDEW;  E DIN VDE
                    0126 (10.97))
Low voltage regulation:  DIN EN 50178 (4.98) (VDE 0160)
                        DIN EN 60146 part 1-1 (3.94)

Certificate for Sunny Boy 2500U

- Underwriters Laboratories Listing Document dated 8 May 2001
NOTICE OF AUTHORIZATION TO APPLY THE UL MARK

Northbrook Office

May 8, 2001

Sma Regelsysteme GmbH
Attn: Mr. Sven Bremicker
Hannoversche Str 1-5
3266 Neisstetal Germany

Our Reference: File E210376, Project 00N8803A
Subject: Sunny Boy SWK-2500U

Dear Mr. Bremicker:

We have completed our engineering investigation under the above project number and find the products comply with the applicable requirements.

This letter temporarily supplements the UL Conformity Assessment Services Inspection Procedure and serves as authorization to apply the UL and C-UL Listing Mark, only at the factory under UL's Conformity Assessment Service Program, to the above products, which are constructed as described below:

Identical to the subject model which was submitted to UL for this investigation, the UL records covering the product will be in the Conformity Assessment Services Inspection Procedure, File E210376, Volume 1 based on the completion of the Initial Production Inspection (IP) that was performed on May 4, 2001.

To provide the manufacturer with the intended authorization to use the UL Mark, the addressee must send a copy of this Notice and all attached material to each manufacturing location as currently authorized in the appropriate UL File Procedure.

This authorization is effective for 90 days only from the date of this Notice and only for products at the indicated manufacturing locations. Records covering the product are now being prepared and will be sent to the indicated manufacturing locations in the near future. Please note that Conformity Assessment Services Procedures are sent to the manufacturers only unless the Applicant specifically requests this document.

Please note: Within Canada, there are federal and local statutes and regulations requiring the use of bilingual product markings. It is the responsibility of the manufacturer (or distributor) to comply with this law. As such, the markings provided in the UL Conformity Assessment Service Procedure may include only the English version. Please contact us if you need assistance with translations or in determining which markings are appropriate for your product.

Products produced, which bear the UL Mark, shall be identical to those evaluated by UL and found to comply with UL's requirements. If changes in construction are discovered, authorization to use the UL Mark may be withdrawn and products that bear the UL Mark may have to be revised (in the field or at the manufacturer's facility) to bring them into compliance with UL's requirements.

Respectfully,

Stephen T Gardner (Ext. 41576)
